Bifida Ferment Lysate

- **INCI Name**: Bifida Ferment Lysate
- Bifida Ferment Lysate is a fermentation product of Bifidobacterium longum, a useful lactic acid bacterium in the intestines.

**Area of Use**
- Moisturizing Preparations
- Night Skin Care Preparations
- Eye Lotions
- Face and Neck Preparations (Excluding Shaving Preparations)
Bifida Ferment Lysate

- Origin microorganism: *Bifidobacterium longum*

*Bifidobacterium* is a beneficial organism present in the digestive system and is closely related to our bodies.

There is a close relationship between human health and this bacterium, and it is said that if a person is stressed or gets sick, the bacterium is reduced.

- Elastic and vibrant skin
- Clear and transparent skin
- Moist and shiny skin
Bifidobacterium longum ?

- Scientific classification

  Kingdom: Bacteria  
  Phylum: Firmicutes  
  Class: Antinobacteria  
  Order: Bifidobacteriales  
  Family: Bifidobacteriaceae  
  Genus: Bifidovacterium  
  Species: B. longum

- Binomial name

  *Bifidovacterium longum*  
  Reuter

*Bifidobacterium longum* is a species of Gram-positive anaerobic branched rod-shaped bacterium which can be found in the intestines of infant humans.

What is Bifida (*Bifidobacterium*)

*Bifidobacterium* is a genus of Gram-positive, non-motile, often branched anaerobic bacteria. They are ubiquitous, endosymbiotic inhabitants of the gastrointestinal tract, vagina and mouth (B. dentium) of mammals and other animals. *Bifidobacteria* are one of the major genera of bacteria that make up the colon flora in mammals. Some *bifidobacteria* are used as probiotics.

Before the 1960s, *Bifidobacterium* species were collectively referred to as "Lactobacillus bifidus"
Bifidobacterium longum?

- Use of Bifida (*Bifidobacterium*)

*Bifidobacteria* are probiotics that naturally colonize in the human gastrointestinal tract (GIT) and vagina. They were first isolated over a hundred years ago from human feces. *Bifidobacterium longum* is one of most important inhabitants in the human body. This bacterium is very helpful because it maintains a normal digestive tract, inhibits the growth of harmful bacteria, and also boosts the immune system.

Bifidobacterium longum?

Research Team
Dr. John Kryon of the University of Cork in Ireland and researchers at McMaster University in Canada.

Results
Report that indoor microorganisms are involved in mental health, such as behavior and mood of living things.

Contents of research
Rats that ate lactobacillus rhamnosus were less stressed and less depressed or anxious than the sterile mouse. In the brain of mice fed Lactobacillus rhamnosus, the mRNA of the gene that produces the neurotransmitter GABA was activated more. The fewer the GABA, the more depressed and constrictive symptoms appear.

In addition, mice fed with a mixture of microbes called Bifidobacterium longum, the symptoms of anxiety and depression improved. This is as a result related to the vagus nerve, the research team said, "This experiment confirms that intestinal microorganisms affect the brain through vagus nerves."

**Abstract**: Reactive skin is characterized by marked sensitivity to physical (heat, cold, wind) or chemical (topically applied products) stimuli and by the impairment of the skin barrier's ability to repair itself. Several lines of evidence suggest that beyond their capacity to positively influence the composition of intestinal microbiota, some probiotic bacteria can modulate the immune system both at local and systemic levels, thereby improving immune defense mechanisms and/or down-regulating immune disorders such as allergies and intestinal inflammation. Several recent human clinical trials clearly suggest that probiotic supplementation might be beneficial to the skin. Using a probiotic lysozyme, *Bifidobacterium longum* sp. extract (BL), we demonstrated first in *vivo*, and then in a clinical trial, that this non-replicating bacteria form applied to the skin was able to improve sensitive skin. The effect of BL was evaluated first on two different models. Using *ex vivo* human skin explant model we found a statistically significant improvement versus placebo in various parameters associated with inflammation such as a decrease in vasodilation, oedema, mast cell degranulation and TNF-alpha release. Moreover, using nerve cell cultures in vitro, we showed that after 6 h of incubation in culture medium (0.3–1%), the probiotic lysozyme significantly inhibited capsaicin-induced CGRP release by neurons. Then, a topical cream containing the active extract was tested in a randomized, double-blind, placebo-controlled trial. Sixty-six female volunteers with reactive skin were randomly given either the cream with the bacterial extract at 10% (n = 33) or the control cream (n = 33). The volunteers applied the cream to the face, arms and legs twice a day for two months. Skin sensitivity was assessed by sting test (lactic acid) and skin barrier recovery was evaluated by measuring trans-epidermal water loss following barrier disruption induced by repeated tape-stripping at D1, D29 and D57. The results demonstrated that the volunteers who applied the cream with bacterial extract had a significant decrease in skin sensitivity at the end of the treatment. Moreover, the treatment led to increase skin resistance against physical and chemical aggression compared to the group of volunteers who applied the control cream. Notably, the number of stripings required to disrupt skin barrier function was significantly increased for volunteers treated with the active cream. Clinical and self-assessment scores revealed a significant decrease in skin dryness after 29 days for volunteers treated with the cream containing the 10% bacterial extract. Since in vitro studies demonstrated that, on one hand, isolate sensitive neurons release less CGRP under capsaicin stimulation in the presence of the bacterial extract and, on the other hand, increased skin resistance in volunteers applying the test cream, we speculate that this new ingredient may decrease skin sensitivity by reducing neuron reactivity and neuron accessibility. The results of this studies demonstrate that this specific bacterial extract has a beneficial effect on reactive skin. These findings suggest that new approaches, based on a bacteria lysozyme, could be developed for the treatment and/or prevention of symptoms related to reactive skin.

**Key words**: aging – *Bifidobacterium* – probiotics – sensitive skin – skin barrier resistance – xerosis

The Protective Effect of Extracts of Bifidobacterium longum against Ultraviolet B in Human Dermal Fibroblasts.
Korea Institute for Skin and Clinical Sciences 2012; 10(4): 887-891

Abstract  
*Bifidobacterium longum* (*B. longum*) is a species of gram-positive anaerobic bacterium which can be found intestines of humans. *B. longum*, a potential probiotic used in the food industry, promotes the health of human intestinal tract by reduction of harmful gram-negative bacteria and toxic molecules. Also, *B. longum* has numerous biological effects, such as anti-cancer, activation of immune response and reduction of DNA damage. Ultraviolet (UV) irradiation has many adverse effects on skin, including inflammation, alteration in the extracellular matrix, cellular senescence and apoptosis. In this study, we investigated the protective effect of *B. longum* extracts against UVB-induced cellular damage in human dermal fibroblasts (HDFs). *B. longum* extracts at concentration 0.01 ~ 0.02% (w/v) did not affect cell viability in HDFs. When UVB-exposed HDFs were treated with *B. longum* extracts, cell viability was substantially enhanced in a dose-dependent manner. To investigate inhibitory effects against cellular senescence of *B. longum* extracts in HDFs, we performed SA-β-gal staining. UVB-exposed HDFs with *B. longum* extracts were decreased SA-β-gal positive cells approximately 40% at the concentration of 0.02% (w/v). Flow cytometry was used to determine changes of cell cycle in *B. longum* extracts treated-HDFs. UVB irradiation slightly increased the percentage of cell population in the sub-G1 phase. However, the proportion of cells in sub-G1 phase were decreased approximately 50% by treatment with *B. longum* extracts. These results suggest that *B. longum* extracts reduce UVB-induced cellular senescence and apoptosis in HDFs. Thus, *B. longum* extracts might be used as a potential agents for protection of UVB-induced skin cell damage.

Bifida Ferment Lysate helps maintain and support skin’s natural microflora and absorbs skin-damaging UV radiation.

Bifida Ferment Lysate is a product of filtration of fermented products of bifidus bacteria and can help to recover skin damaged by harmful substances. The use of Bifida Ferment Lysate can be expected to strengthen barriers to skin, increase elasticity of skin, and change to lively skin.
